# Reports A bioinformatics approach to identify telomere sequences

Indira Somanathan<sup>1</sup> & Chris Baysdorfer<sup>\*,1</sup> <sup>1</sup>Department of Biological Sciences, California State University East Bay, Hayward, CA, USA

BioTechniques 65: 20-25 (July 2018) 10.2144/btn-2018-0057 Keywords: bioinformatics • next-generation sequencing • NGS • sequence repeat finder • SERF • tandem repeats • telomere

Conventional approaches to identify a telomere motif in a new genome are laborious and time-intensive. An efficient new methodology based on next-generation sequencing (NGS), de novo sequence repeat finder (SERF) and fluorescence in situ hybridization (FISH) is presented. Unlike existing heuristic approaches, SERF utilizes an exhaustive analysis of raw NGS reads or assembled contigs for rapid de novo detection of conserved tandem repeats representing telomere motifs. SERF was validated using the NGS data from Ipheion uniflorum and Allium cepa with known telomere motifs. The analysis program was then used on NGS data to investigate the telomere motifs in several additional plant species and together with FISH proved to be an efficient approach to identify as yet unknown telomere motifs.

## Introduction

Eukaryotic linear chromosome ends are characterized by telomeres, which are generally made up of long tracts of minisatellite tandem repeats [1]. Telomeres are maintained by telomerase, a reverse transcriptase-based end maintenance system [2]. Telomeres help to prevent the loss of essential genetic information from the chromosome ends resulting from the incomplete replication of the lagging strand of chromosomal DNA and help to avoid detrimental chromosomal end-to-end fusions by distinguishing the double-stranded DNA (dsDNA) breaks from the native ends of the chromosomes [3]. Telomeres, together with their associated proteins, secure and stop the degradation of the chromosomal ends by various nucleolytic enzymes, as reviewed in de Lange [4]. Thus, telomeres maintain the integrity and stability of chromosomes.

The telomere repeat motif (TTTAGGG),, discovered in Arabidopsis thaliana [5], is considered to be the consensus telomere motif for most land plants [6]. Similarly, other groups of organisms have shown conservation of their telomere motifs. However, there are a few exceptions to the ancestral-type consensus telomere motif. Drosophila melanogaster, a dipteran, lacks telomerase and the insect-type telomere repeat motif (TTAGG), [7,8]. Its telomeres have been replaced by three different types of telomere-specific non-long terminal repeat (non-LTR) retrotransposons [9], namely, HeT-A [10], TART [11] and TAHRE [12], which perform the telomere functions. In various species of algae, telomere repeat motif sequences are seen to differ slightly from the land plant telomere motif (TTTAGGG), [13]. For example, in the green alga Chlamydomonas reinhardtii, a more T-rich telomere repeat motif (TTTTAGGG), has been detected [14]. A telomere repeat motif switch identical to that found in Chlamydomonas-type was also seen in a few species of algae from the genus Klebsormidium [15,16].

Telomere motif evolution has also been demonstrated across various groups of land plants [17]. The Arabidopsis-type telomere is lost in Cestrum elegans from the family Solanaceae [18] and is replaced by an unusual 10 base pair (bp) telomere motif (TTTTTAGGG), maintained by telomerase [19]. Yet, many model plant species for telomere studies from this family, such as Nicotiana tabacum, Solanum lycopersicum and Solanum tuberosum, carry the ancestral-type telomere motif (TTTAGGG), at their chromosome termini [20-22]. Telomere divergence has also been shown to occur in monocots, especially in the order Asparagales. In the family Asphodelaceae, plants of the genus Aloe lack the Arabidopsis-type (TTTAGGG), telomere motif [23] and instead have the human-type (TTAGGG), [24]. Different types of telomere motifs are discovered in the family Amaryllidaceae. For example, in Ipheion uniflorum, the canonical Arabidopsis-type telomere motif is replaced by human-type [25], while in Allium cepa and related species, a unique 12 base pair telomere motif (CTCGGTTATGGG), [26] has replaced both the Arabidopsis-type (TTTAGGG), [27,28], and the human-type (TTAGGG), [25,29] telomere motifs. It took more than a decade of extensive research to finally identify the distinct telomere motifs in the genera Cestrum and Allium.

## METHOD SUMMARY

Here we introduce a bioinformatics-based methodology for the rapid de novo detection of the most probable telomere motifs in genomes of any size. Raw unassembled genomic data from next-generation sequencers are analyzed using the newly developed SERF de novo sequence analysis algorithm to identify a culled set of putative telomere motifs based on their biological characteristics. The cytological validation of these motifs using fluorescence in situ hybridization followed by its detection using confocal microscopy can expedite the identification of true telomere sequence with fewer wet-lab iterations.

20

A number of specific approaches to quantify human telomere length [30] from whole genome squencing (WGS) data use the known telomere motif (TTAGGG)<sub>n</sub>. The few *de novo* repeat detection tools [31–33] available are not equipped with a probable telomere motif detection algorithm from the NGS sampling data or WGS data. Consequently, efforts to detect telomere motifs employ time-intensive laboratory protocols and complex computational methods [26,34].

Future efforts to identify as yet unknown telomere motifs in a variety of genomes can be expedited using bioinformatics. We present a simple and efficient methodology that utilizes NGS data in conjunction with sequence repeat finder (SERF) algorithms, which is tailored towards identifying the probable conserved telomere repeat motifs and their subsequent cytological validation using fluorescence *in situ* hybridization (FISH) [35] (Figure 1).

## Materials & methods

#### Plant materials

Plant materials used in this research include Ipheion uniflorum, Allium cepa, Narcissus jonquilla and Muscari comosum, obtained from commercial sources.

#### Isolation of total genomic DNA

Total genomic DNA was isolated from young leaves of these plants using the Qiagen DNeasy plant mini kit (Hilden, Germany) as per manufacturer's protocols. Approximately 100 mg (wet weight) of the leaf tissue was used for each of the isolations.

#### Next-generation sequencing

Genome sampling data was collected in multiple runs from *A. cepa* (GenBank Sequence Read Archive [SRA] accession numbers: SRX3381812, SRX3381811 and SRX3381814) and *N. jonquilla* (GenBank SRA accession numbers: SRX3381816 and SRX3381815) and in single runs from *I. uniflorum* (GenBank SRA accession number: SRX3381813) and *M. comosum* (GenBank SRA accession number: SRX3381817) using the Ion Torrent nextgeneration sequencing (NGS) platform (Life Technologies, CA, USA), as per manufacturer's instructions. *De novo* assemblies for *A. cepa* and *I. uniflorum* were performed using the software SeqMan NGen (www. dnastar.com). Previously sampled plant genomes from more than 20 species belonging to the families *Solanaceae*, *Liliaceae*, *Smilacaceae* and *Velloziaceae* (Unpublished Data) were also used to validate the telomere motif identification methodology (see Table 4).

## SERF *de novo* telomere sequence analysis

Consensus sequences from the whole genome assemblies in FASTA format and the raw NGS reads data in FASTQ format were separately analyzed by the sequence repeat finder (SERF) analysis platform (bioserf.org) to *de novo* identify and extract contiguous conserved tandem repeats varying in size from 5–15 base pairs. Genomes of *I. uniflorum* with human-type (TTAGGG)<sub>n</sub> [25] and *A. cepa* with a unique 12 base pair (CTCGGTTATGGG)<sub>n</sub> [26] telomere repeat motifs were used as positive controls for the initial validation of the SERF algorithm.

Homopolymeric nucleotide tracts and supersets of repeats were filtered out from the analysis results. This analysis looked for a pattern of organization (contiguous versus scattered), positional distribution of the repeats within the contigs or reads, and the frequency of the conserved repeat motifs in these sequences. The quality metric concept employed in SERF reflected the percentage of the individual read or contig length occupied by the identified contiguous repeats. A similar approach was used in A. cepa telomere motif identification [26]. Permutative combinations were analyzed, and repeats were clustered based on the size, position and type of base pair. Based on the assumptions that telomeres are poorly represented in genome sampling, and that the reads generated using the lon

Figure 1. Workflow: NGS–SERF-based approach. Putative telomere repeat motif analysis by SERF using the genomic NGS data as raw reads (FASTQ) or contig assembly (FASTA) followed by cytological validation with FISH.

FISH: Fluorescence *in situ* hybridization; NGS: Next-generation sequencing; SERF: Sequence repeat finder.

Torrent are generally short in length, an initial protocol of 2-5-15-90-TG-contiguous (minimum number of contiguous repeatsminimum base pair size-maximum base pair size-90% quality metric-TG richnesscontiguous mode) was employed. Emphasis was given to the quality metric rather than the number of tandem telomere motifs to analyze the assembled contigs in I.uniflorum. An identical protocol successfully identified the respective telomere motifs from unassembled NGS reads of *I. uniflorum* and A. cepa with a high quality metric. The same protocol was used on all other species tested. Additional information on SERF can be found in the Supplementary material (Figure S1) and from bioserf.org.

## Probe synthesis for FISH on *N. jonquilla*

11-dUTP biotinylated probes were synthesized using PCR with *N. jonquilla* genomic DNA for (A) the unique 15 bp (GAGGGTGCACTCACG)<sub>n</sub> and (B) humantype (TTAGGG)<sub>n</sub> repeats identified by SERF analysis on its raw NGS reads. The following primers were used: for repeat (A): 5' ACTCACGGAGGGTGCACTCACG 3' (for), 5' CGTGAGTGCACCCTCCGTGAGT 3' (rev), and for repeat (B): 5' TTAGGGTTAGGGT-TAGGGTTAGGG 3' (for) and 5' CCCTA-ACCCTAACCCTAACCCTAA 3' (rev). The lengths of the probes were between 200 and 400 bp.

#### Preparation of metaphase chromosome spreads of *N. jonquilla*

Young root tips (3–5 days old) from *N. jonquilla* bulbs were arrested in metaphase by ice cold water treatment, fixed in freshly prepared Carnoy's solution I, and spread by squashing [36]. Metaphase chromosome spreads on slides were immediately frozen at -80°C for 5–10 min before they were fixed in 4% formaldehyde in 2XSSC (saline sodium citrate) for 10 min. Slides were washed twice (5 min each) in 2XSSC followed by 95% ethanol fixation for another 10 min. Slides were air-dried, and those with good metaphase spreads were selected for performing FISH.

## *In situ* hybridization on *N. jonquilla* metaphase chromosome spreads

A slightly modified version of the FISH protocol by Fajkus *et al.* [26] was followed. First, 30  $\mu$ l/slide of hybridization mix, which included 50% (v/v) deionized formamide (Applied Biosystems, USA), 10% (w/v) dextran sulphate in 2×SSC, 200–300 ng of the biotinylated probe, 50× salmon sperm carrier DNA (stock 10 mg/ml; 5 Prime -> 3 Prime, Inc., CO, USA) was prepared. The chromosomal DNA on the slides, together with the probe in the hybridization mixture, was denatured in a thermocycler for 3 min at 80°C. The slides were promptly moved to a moist chamber kept at 35°C in a hybridization chamber and hybridized overnight for 12-16 h. The cover slip was carefully removed by dipping in 2×SSC at 42°C. Posthybridization washes were comprised of 3 × 5 min each at 42°C in 40% formamide in  $2 \times SSC$ , pH 7;  $1 \times 5$  min in  $2 \times SSC$  at  $42^{\circ}C$ ; 1 × 10 min in 2×SSC at room temperature. Slides were incubated with streptavidin 680-I dye conjugate (Abnova, Taiwan) at 1:200 dilution in 2×SSC for 40 min in a 37°C moist chamber and excess conjugate mix was washed off in 2×SSC at 45°C for 10 min. Finally, the slides were air-dried and counterstained with ProLong® Diamond Antifade Mountant with DAPI (4',6-diamidino-2 phenylindole) by Life Technologies. Hybridization signals were imaged using a Leica TCS SP8 Confocal Microscope (Wetzlar, Germany).

### **Results & discussion**

A SERF protocol of 2-5-15-90-TG-contiguous was used to validate the human-type telomere motif from the unassembled NGS reads and contig assembly of *I. uniflorum*. SERF analysis successfully identified its telomere motif despite the fact that only 1.4% (0.13 Gbp/9.44 Gbp) of the genome was available for analysis (Figure 2).

Table 1 shows the identification of the human-type telomere motif from the contig assembly of *I. uniflorum.* The analysis retrieved a single short contig of 59 base pairs in length consisting of 14 reads and harboring nine of the human-type (TTAGGG) telomere repeat motifs in tandem with a high quality metric of 91%. SERF analysis on the unassembled NGS reads of *I. uniflorum* has also detected an identical repeat motif output from multiple reads with high quality metric (data not shown).

SERF analysis detected and retrieved a single contig of 39 base pairs from *A. cepa*'s contig assembly of the pooled read sets with the known *Allium* telomere repeat motif (Table 2). The identified telomere motif from the assembled contig has a high quality metric of 92% and is rich in T and G as well. The telomere repeat motif in its various permutative forms was also located in many

**Figure 2. Telomere motif detection of** *Ipheion uniflorum* **with NGS–SERF-based approach.** Detection of the human-type (TTAGGG)<sub>n</sub> telomere repeat motif in *I. uniflorum* from its raw NGS reads and contig assembly using SERF.

NGS: Next-generation sequencing; SERF: Sequence repeat finder.

reads of single *A. cepa* NGS runs using the same protocol (Table 3). Depending on the number of NGS reads that harbor these extended repeats, assembly may not always yield a contig with these repeat motifs, which makes analysis on unassembled NGS data more desirable. WGS can overcome this difficulty and can generate a sufficient number of reads to form contig representing the telomere, enabling the measurement of the telomere content in the genome [30,37].

Sample output of the SERF analysis on one of the raw NGS sampling data sets of *A. cepa* using the protocol 2-5-15-90-TG-contiguous for a selected quality metric of 90% (Figure S2), FISH on its metaphase chromosome spreads (Figure S3) and the FISH methods are included in the Supplementary Material.

An extensive study of telomere repeat motif identification was also undertaken on the unassembled NGS data from genomic sampling of over 20 plant species from diverse families such as Amaryllidaceae, Hyacinthaceae, Liliaceae, Solanaceae, Smilacaceae and Velloziaceae (Table 4). Many of the plants analyzed have previously identified or probable consensus telomere repeat motifs of their respective families or genera. SERF analysis on F. imperialis predominantly detected the presence of Arabidopsis-type telomere repeat motifs, but combination repeats such as TTTAGGGTTAGGG and TTTAGGGTT-TAGGGG were also detected, but with a lower quality metric (44 and 54%). SERF analysis also identified both human-type (TTAGGG), and Bombyx-type (TTAGG), putative telomere motifs from a single read in F. pudica (41 and 48%) and Arabidopsis-type and Bombyx-type as putative telomere motifs in T. nana (100 and 98%). Analysis of Xerophyta humilis from the family Velloziaceae identified (TTTAGGG), and (TTTTAGG), as probable telomere repeat motifs with a high-quality metric (100 and 84%). The probable telomere repeat motifs (Table 4, superscript 5) identified by SERF analysis from various species require further

cytological confirmation. Most species that were analyzed had unassembled NGS data equivalent to 50–150 Mbp and were processed by SERF in a few hours.

In N. jonguilla and M. comosum from the order Asparagales, the Arabidopsis-type and human-type telomere repeat motifs were originally shown to be absent from their genome [38]. Later studies, however, did suggest the presence of these two types of telomere repeat motifs with an abundance of the human-type in Narcissus triandrus and Muscari neglectum telomeres [39]. SERF analysis on N. jonquilla's raw NGS data sets identified a 15 bp unique conserved tandem repeat motif (GAGGGT-GCACTCACG) on a read with a high quality metric (90%) in addition to the human-type telomere repeat motif (TTAGGG) with 90% (Table 5). Higher probability of human-type motif as N. jonguilla telomere motif is evident from its abundance in the PCR amplification products (Figure S4). Analysis of the raw NGS data of *M. comosum* also revealed the abundance of human-type telomere repeat motif in multiple reads (Table 4). A few Arabidopsis-type repeats in tandem were also retrieved, but with a low quality metric.

The human-type and unique repeats identified by SERF analysis were subjected to cytological validation on *N. jonquilla* metaphase chromosome spreads using FISH. FISH with probes synthesized using the repeat motif (GAGGGTGCACTCACG)<sub>n</sub> did not yield any telomere-specific signals (data not shown), whereas FISH performed using probes specific to the human-type telomere repeat motif (TTAGGG)<sub>n</sub> generated clear signals from the telomeres on the metaphase chromosome spreads of *N. jonquilla* (Figure 3).

Telomere repeat motifs identified by SERF from the analysis of plant genomes (Table 4) are deposited in the SERFDB database (bioserf.org). Some motifs already have cytological validation from previous work, while others require such validation.

The majority of land plants were initially thought to have the *Arabidopsis*-type telomere motifs at their chromosome termini, but the universality of this ancestral motif came under question once its absence from telomeres had been detected in monocots from the families *Amaryllidaceae* (earlier known as *Alliaceae*) [28] and *Asphodelaceae* [23], both belonging to the order Asparagales. Fuch *et al.* (1995) [28] showed that plants in the genus *Allium* from the *Amaryllidaceae* family have completely lost the typical ancestral-type telomere repeat motif (TTTAGGG)<sub>n</sub> from both telomeres and interstitial regions. These evolutionary switches in telomere motif sequence have been widespread in the order Asparagales and the typical consensus plant telomere

motifs are replaced in many plants with unique repeat sequences that were never before detected [26].

Conventional methods to find an unknown telomere motif in a new genome are challenging. A positive outcome results only if the organism under investigation maintains one (or a combination) of the known consensus telomere motifs in its

chromosome termini. The recent detection of novel telomere motifs, especially in the order Asparagales [26], illustrates the challenge and warrants the need to switch from the conventional approach to one that utilizes modern sequencing technology and analysis platforms for an effective utilization of available resources. Such a shift is occurring and is seen in the discovery of the telomere motifs of *C. elegans* [19] and *A. cepa* [26,34].

The SERF analysis platform utilized here employs multiple features to increase its accuracy and efficiency in telomere repeat motif identification. The selection of tandem repeats rich in T and G [14], enabled the elimination of an inordinate number of irrelevant tandem repeat motifs. As guaninerich telomere motifs are a hallmark of telomeres [40,41], removal of repeats without a G-rich region was important in the telomere motif search. The introduction of the quality metric facilitated identification of tandem repeat motifs with telomere characteristics using the SERF protocol (2-5-15-90%-TG-contiguous). Additional features such as clustering, identification of permutations, homopolymeric tracts and supersets, helped in the filtering of an overwhelming number of repeats that otherwise would have crowded the analysis results. These specific search attributes resulted in the successful identification of telomere motifs from both contig assembly and raw NGS reads. Use of *I. uniflorum* and *A. cepa* with known telomere motifs as positive controls enabled the fine-tuning of the SERF algorithm to identify the most probable telomere motifs from any genome of interest.

Telomere repeat motif analysis on the positive control plants emphasizes the need to rely more on raw NGS reads rather than on the genome assemblies due to assembly process excluding some repeated sequences and contigs with low read depth. Hence, SERF analysis primarily utilized the raw NGS data on all of the additional species investigated here. The analysis of multiple species (Table 4) has either reinforced earlier findings [29,38,39,42,43] or identified other potential telomere repeat motifs bioinformatically, requiring further cytological confirmation.

In the standard SERF protocol (2-5-15-90-TG-contiguous), the quality metric of 90% successfully identified the known or most probable telomere motif from the majority of the plants studied. However, in a few instances variations in quality metric were required to address sequencing errors in the raw NGS reads and when the repeat motifs identified were longer, as in the case of *F. imperialis, C. elegans* and *A. cepa* 

(Table 4). Our method enabled the rapid detection of two potential telomere repeat motifs from *N. jonquilla* and cytological validation confirmed that only the human-type repeat is present at the telomeres (Figure 3).

This research has demonstrated that the discovery of probable conserved telomere repeat motifs in any genome can be expedited by using SERF *de novo* tandem repeat analysis of the raw NGS data, followed by cytological validation using FISH. This methodology is cost efficient and can be used for the rapid detection of as yet unknown telomere motifs in genomes.

## Author contributions

IS and CB conceived and developed the NGS, SERF and FISH based approach. IS and CB performed genomic DNA extraction and NGS. IS performed SERF analysis and FISH-based cytological validation of the approach. IS wrote the paper and CB supervised the study and revised the manuscript.

## Acknowledgements

This research would not have been possible without the NGS sequencing data from CSU East Bay Biocore Lab and the SERF analysis platform from bioserf.org. We acknowledge and thank them for their valuable support.
